HASL SURFACE AIR SAMPLING PROGRAM

Gamma Activity Measurements for March 1970

Attached are the results of the gamma activity analyses of filters from the HASL Surface Air Sampling Program for the month of March 1970.

The weekly samples are composited on a monthly basis and counted on an 8" x 4" sodium iodide (Tl) crystal. The integrated response between 100 Kev and 3.0 Mev is corrected by the average detection efficiency (35%) of the gamma photons present in fallout. The results are reported in units of photons per minute per 1000 standard cubic meters (sea level conditions of the ICAO Atmosphere).
