INTRODUCTION

Information on geographic distribution of cancer has been particularly useful in developing and testing etiologic hypotheses. International variation is often striking, and has provided many leads to environmental and ethnic factors involved in the origins of cancer. Less well known is the geographic variation for cancer within countries. In the United States, cancer mortality statistics have been analyzed for geographic divisions and states, but no comprehensive surveys of cancer have been made on a smaller geographic scale. Recently, a series of magnetic tapes from the National Center for Health Statistics enabled the Epidemiology Branch of the National Cancer Institute to analyze cancer mortality for all counties of the contiguous United States, 1950-69, by age, race, sex, and site of cancer.

This report presents, for each county in the United States, the total number of cancer deaths and age-adjusted death rates according to sex and race (whites and nonwhites) over the 20-year period, 1950-69. As standards for comparison, age-adjusted cancer death rates are given also for the 48 contiguous states and for the total United States. In an earlier publication (National Cancer Institute Monograph No. 33) age-adjusted rates were computed for each state and nationwide for the 18 year period, 1950-67. The current report has the advantage of two additional calendar years of mortality data, and improved population estimates which became available recently from the 1970 census.

As the geographic unit for study, the county has advantages over larger areas in the greater homogeneity of its population with respect to demographic characteristics and environmental exposures. Some counties have populations which are too small to obtain reliable mortality rates for certain cancers, but sufficient numbers are generally available to calculate meaningful values. Furthermore, the mortality data can be correlated with demographic and environmental variables collected by governmental and other agencies, and available on a county level.

The mortality data in this report may be used for various epidemiologic purposes. It should be possible to generate clues or hypotheses to the origin of certain cancers by identifying counties and groups of counties with high rates, and determining if these areas share certain demographic or environmental variables. In approaching from the opposite direction, it should be possible to evaluate ideas or hypotheses by identifying counties with unusual environmental or demographic characteristics, and determining whether these areas have peculiarities in the frequency of particular cancers. To help visualize the distribution of counties with significantly high rates throughout the country, a series of illustrative maps is being prepared by the Epidemiology Branch, and will be published as an atlas to supplement this report. Finally, the information herein should be useful to public health and administrative officials concerned with the impact of cancer in various communities in the United States.

JOSEPH F. FRAUMENI, JR., M.D.

ACKNOWLEDGEMENTS

We are indebted to Dr. Robert W. Miller, Chief of the Epidemiology Branch and Dr. Joseph F. Fraumeni, Jr., Associate Chief, for their encouragement in this endeavor. We wish to thank Dr. Robert N. Hoover for his suggestions with regard to the presentation of this material, Miss Anya Shevchenko for her programming assistance, and Mrs. Melvina Harren for her most efficient assistance in preparing the population files.

THOMAS J. MASON, PH.D.

Epidemiology Branch
National Cancer Institute

METHODS

Average annual age-adjusted mortality rates (per 100,000) were calculated for counties listed on the death certificate as the county of usual residence by site, race and sex with the toal U.S. population for 1960 used as the standard for the period 1950-1969. Rates have also been calculated for each of the 48 contiguous states and for the total United States, which includes Alaska and Hawaii. White and nonwhite county populations at risk were taken from the 1950, 1960, and 1970 censuses (1-3). Intercensal estimates were derived by linear interpolation. The counties of Alaska and Hawaii were not included since mortality data were first available in 1959. The District of Columbia has been reported as a separate entity. The Sixth Revision of the International Classification of Diseases (I.C.D.)[4] has been used for all sites.

The age-adjusted rate was calculated using the following:

$$S(i,t) = \frac{D(i,t)}{R(i,t)}$$

$$A(t) = \sum_{i=1}^{n} \frac{S(i,t)\ P(i)}{\sum_{i=1}^{n} P(i)} \cdot 100{,}000$$

$S(i,t)$ = The age-specific death rate in age group i. over t years.

$A(t)$ = The age-adjusted death rate over t years.

$D(i,t)$ = The number dead in age group i over t years.

$R(i,t)$ = The number in age group i in the population at risk over t years.

$P(i)$ = The number in age group i in the standard population in the base year.

t = The number of years observed, which is 20.

i = A particular age group m years wide.

n = The number of age groups.

For any given site and race, an individual county was included if there was at least one death for either sex. Blanks were used to denote no mortality for the particular site, race and sex. If the county rate was less than 0.049 per 100,000, it was reported 0.0. All state rates have been reported to two decimal places.

Selected counties were combined in the states of New York, Wisconsin, and Virginia: in New York, because deaths in New York City were coded as having occurred in New York County; in Wisconsin, because a new county was created; and in Virginia, because there were cities whose populations came from more than one county. These specific counties have been given in footnotes to the State-County Identification Codes.

Because race was not reported on death certificates in the State of New Jersey in 1962 and 1963, the mortality reported during this time was distributed to be consistent with the reported county, race, site and sex specific mortality for the years 1960, 1961, 1964, and 1965.
